.htaccess for PHP projects: friendly URLs and redirects

Frameworks, Composer & Git Created on **October 10, 2026** 3 min read

The **.htaccess** file is where you tell the server how to treat addresses: send every request to a single `index.php` file (friendly URLs), redirect one address to another, and hide what must not be public. It is plain text, sits in the site folder, and the server reads it on every request.

What each need calls for

I want…	Directive	Note
Friendly URLs (a single entry point)	RewriteRule to index.php	It is what most PHP applications expect. First block below.
To move a page	Redirect 301	The 301 tells search engines the move is permanent.
One address for the site (with or without www)	RewriteCond and RewriteRule	Stops the same site living at two addresses.
To force https	RewriteCond and RewriteRule	Already described in **redirecting HTTP to HTTPS**.
To hide files such as .env	FilesMatch	Last block below.

The blocks used most

Friendly URLs: anything that is not an existing file or folder goes to `index.php`.

```
RewriteEngine On
RewriteCond %{REQUEST_FILENAME} !-f
RewriteCond %{REQUEST_FILENAME} !-d
RewriteRule ^ index.php [L]
```

A page that moved:

```
Redirect 301 /old-page.html /new-page.html
```

No www only (swap in your own name, keeping the dots written as shown):

```
RewriteEngine On
RewriteCond %{HTTP_HOST} ^www\.yourdomain\.tld$ [NC]
RewriteRule ^(.*)$ https://yourdomain.tld/$1 [R=301,L]
```

Hide files that start with a dot (such as .env or .git):

```
<FilesMatch "^\.">
Require all denied
</FilesMatch>
```

Before you touch it

1. **Copy the .htaccess** before editing it: click it and choose copy in the File Manager.
2. **Change one thing at a time** and open the site after every change. A typing error in a single character gives a 500 error on the whole site.
3. **Test with 302 and switch to 301 at the end.** The browser remembers a 301 for a long time; if you get the destination wrong, it keeps going to the wrong place even after you fix it. Test in a private window.
4. Order matters: redirects go **before** the index.php block.

Two closing notes. A `.htaccess` applies to the folder it sits in and the folders inside it, and the rules of an inner folder run **in addition to** the ones above. And write a comment (a line starting with `#`) explaining each block you add: a year from now, nobody remembers why it is there.

WordPress writes its own block

, between the lines “BEGIN WordPress” and “END WordPress”. Do not edit inside it: WordPress rewrites it. Put your rules above or below. If WordPress addresses return 404, see **permalinks and the 404 that follows**.

Got a 500 after saving?

Go back to the copy. The error nearly always comes from the last line you added. See also **error 403: permissions, .htaccess and blocked IPs** and, to redirect without losing your Google positions, **301 redirects**.

NEED A HAND?

Saved the .htaccess and the site gave a 500 error? Tell us the time and what you added.
